

## Mitochondrial respiration in peripheral blood mononuclear cells correlates with depressive subsymptoms and severity of major depression

Karabatsiakos A, Böck C, Salinas-Manrique J, Kolassa S, Calzia E, Dietrich DE, Kolassa IT

### High-resolution respirometry of cryopreserved lymphocytes as a diagnostic tool for major depression (MD)

**Figure 1.** Boxplots of group-wise comparison of respiration in PBMCs from MD patients ( $N = 19$ ) and control subjects ( $N = 19$ ) characterized by mitochondrial oxygen flux ( $I_{O_2}$ ) per cell. Circles and triangles represent statistical outliers of the respective groups. Asterisk (\*) indicates significant group differences on an alpha level of 0.05 (one-tailed Mann-Whitney U test or Student's independent t-test). MD, major depression; PBMCs, peripheral blood mononuclear cells; SRC, spare respiratory capacity

**The significant decrease of ET-capacity and excess E-R capacity factor indicates that cells of acutely depressed patients have a reduced capacity of mitochondrial respiration that contribute to the pathophysiology and/or aetiology of depressive symptoms**
